STAFA CELLULAR THERAPY

When Cells are the Cure

Information technology solutions for efficient, safe, compliant, and logistics-friendly cell acquisition, manufacture, and therapy.

Doing for Cell Therapy what the EMRs Don't Do!

www.stafa-ct.com

Why Stafa CT?

Solutions that:

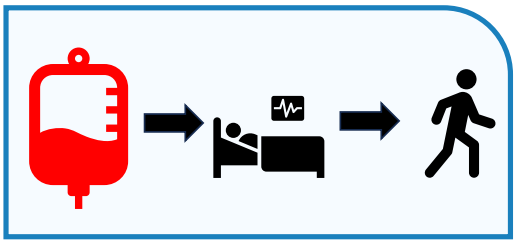

- Provide comprehensive information technology support of all required stem cell transplantation and cell therapy (TCT) functions;
- Complement and integrate specialty functions not supported by standard EMRs;
- Extensively use interfaces and information transfer to and from institutional systems and devices; are EMR agnostic; and connect using HL7 and HL7 FHIR;
- Consolidate all TCT information to a single database and system;
- Eliminate or minimize need for multiple data entry by clinical and research staff to submit to required agencies (CIBMTR, FACT, BioPharma, QA, billing, long term follow-up, and more); provide data for research and analysis to multiple stakeholders as needed;
- Monitor and maintain program compliance with FACT and other standards;
- Deliver continuous program operations intelligence for administrators and physician leadership.

Structure – an Integrated Modular Architecture

TCT is a department that necessarily needs data from apheresis units and machines, TCT labs, and external sources, and has specialized reporting, communication and billing requirements in an extremely high mortality and high dollar zone. Stafa CT backstops safety and quality. It then provides efficiency that saves time and impacts lives.

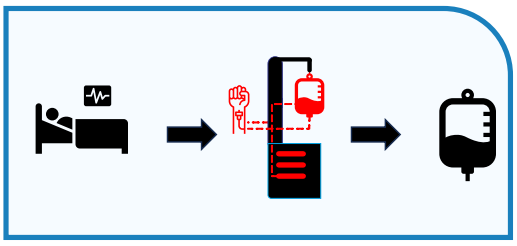

Complete Coverage with Specialty-Driven Modules—Implement in Sequence based on Your Priorities and Workflows

Stafa CT is engineered in function-driven modules that offer comprehensive coverage of all information required by a state-of-the-art TCT program. This solution is uniquely comprehensive. It addresses the many functions needed in an efficient TCT program that are not available in an EMR. All the modules are fully integrated and support real-time information sharing between physically dispersed TCT department components and institutional systems. Workflows are compatible with and adjustable to meet local practice. Modules can be implemented alone or in sequence compatible with institutional priorities.

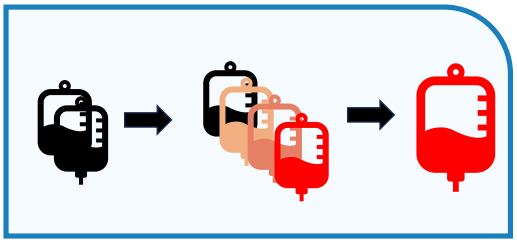

Stafa Clinical

Stafa CT Clinical is designed to support key elements of information required for physician decisions in the transplant and cell therapy process and the collection and updating of all information required by CIBMTR and minimizes manual data entry. It follows the clinical workflow of clinicians, coordinators, and billing staff, and imports relevant data from EMR and other institutional systems through interfaces. Donor/recipient matching data is shown in customized data displays to speed product selection and accuracy. Long term follow up (LTFU) data can be easily captured, and software can be adapted to LTFU needs as they change for treatment modalities.

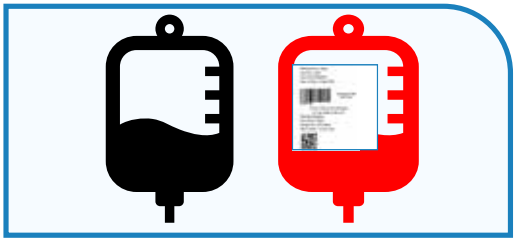

Stafa Apheresis

Stafa Apheresis supports cell collection procedure scheduling, collection monitoring, and completeness, and connects with, acquires, and stores data from Optia® (Terumo) machines to assess collection efficiency. It acquires all technician and nurse input data required for FACT reporting. It also serves as the clinical record for all aspects of therapeutic apheresis procedures. It notifies Stafa CTL (Stafa lab/manufacturing) of all activities in real time, managing cross functional and departmental workflow and planning. It delivers all data (including apheresis machine data) to the EMR via an interface and helps avoid or decrease nursing and technician data entry into disparate EMR, Labeling, Apheresis, Scheduling, and BioPharma or Sponsor systems. Stafa Apheresis can also be configured to help provide protocol-specific optimization pointers.

Stafa Cellular Therapy Laboratory (CTL / Manufacturing)

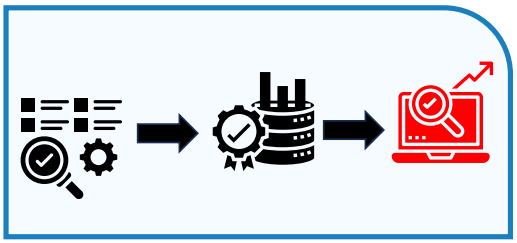

Stafa CTL focuses on the workflow and information through the laboratory/manufacturing process. It allows upload and customization of detailed protocols to structure technician workflow for both minimal manipulation and complex product production of all cell types (PBPC, marrow, CTL, CAR-T, NK-CAR). It integrates complex calculations (total cell number, T-cell subsets, viability) across the protocol timeline, and supports customized product and reference vial storage and retrieval designs. Stafa CTL provides storage management functions and monitors the complete chain-of custody procedures for both institutional and external transport to other transplant centers or pharmaceutical manufactures. Stafa CTL improves the quality and reproducibility of cell manufacture and provides real-time feedback and compliance.

Stafa ISBT 128

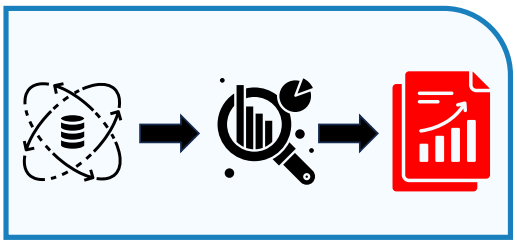

Stafa ISBT 128 uses internationally recognized standards to manage, print, and label products and subproducts created during processing, cryo-storage, and transportation. It supports SEC (Single European Code) and GRID (Global Registration Identifier for Donors). Stafa ISBT 128 supports all aspects of traceability including bar code readers and audit trails.

Stafa ISBT fully integrates with Stafa's CTL and Apheresis modules and supports barcode scanning.

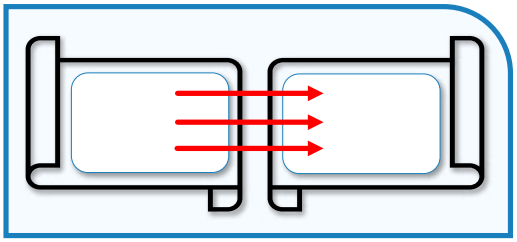

Stafa FACT & Quality Monitoring

Engineered to auto-audit data in Stafa CT as it is acquired, and to interpret both FACT and protocol-specific quality rules for the staff, Stafa FACT and Quality Monitoring is used both to set up a center for FACT inspections, and to manage all clinical and lab processes in the center. It acquires quality metrics from all other modules in Stafa and implements standards required by FACT and CIBMTR. It reports deviations/violations; monitors institutional deviation barriers such as infection frequency, collection adequacy, toxicity, and survival endpoints; and provides workflows for corrective action and management. This module uniquely provides a continuous self-auditing and quality management mechanism across all aspects of the cell therapy process.

Stafa Analytics and Reporting

Stafa Data Analytics delivers commonly requested standard reports and supports design of custom institutional reports as requested. TCT centers can also create and share their own reports.

Stafa nCartes

nCartes is a specialty product that focuses on the delivery of data from EMR to sponsors and organizations. This is used in the Stafa Cell Therapy world in

Operations — collections related data (IDMs, apheresis machine data, labs, subject and product data) can be delivered to manufacturers, eliminating data entry for lab and apheresis nurses and techs;

CIBMTR — data can be autopopulated to forms to be delivered to CIBMTR;

Clinical Research — sponsor forms and information can be provisioned through automated searches, provided for review as appropriate, and transmitted to sponsor systems (EHR to EDC).

These abilities and searches cover both structured data (eg. common lab results) and unstructured data (path reports, notes, etc.). Uniquely, any data sent to sponsors or authorities is fully available to the originating center in Stafa.

Stafa CT solutions offer a full and complete suite of cloud-available products to manage the "vein to vein and outcomes" processes for cell therapy.

The modular availability of solutions in Stafa CT helps your center move up the path to high-quality cutting-edge cell therapy management in an incremental, manageable, approach.

If you are handling the management of processes in quality, apheresis, lab, manufacturing, clinical trials, cell infusions, and outcomes in cell therapy, Stafa CT is a necessity for your operations.
